

Modelling of flow-drill screw connections in large-scale crash analyses

Johan Kolstø Sønstabø, PhD, Enodo

David Morin, Associate professor, Simlab (NTNU)
Magnus Langseth, Professor, Simlab (NTNU)

Enodo

Outline

- Context and motivation
- Macroscopic modelling of FDS
- Calibration and validation procedure
- Component test simulation
- Remarks

Context

- Lightweight vehicle design.
- Many dissimilar materials.
- Different joining techniques utilized.
- Flow-Drill Screw (FDS) connections.

FDS

- Aluminium ablation castings
- Aluminium GDC castings
- Aluminium extrusions
- Aluminium sheets
- UHS steel
- Steel sheets

The FDS process

Flow-drill screw =
Friction drilling + thread forming + screw driving

- 1) Heating
- 2) Penetration
- 3) Extrusion forming
- 4) Thread forming
- 5) Screw driving
- 6) Tightening

Motivation

Large-scale finite element simulation

Simplified macroscopic modelling techniques required:

- Low CPU cost.
- Reasonable calibration procedure.

Macroscopic modelling of FDS

Macroscopic modelling of FDS

- Connection modelled with `*CONSTRAINED_SPR2`.
 - Diameter.
 - 3 tension parameters.
 - 3 shear parameters.
 - 3 “mixed” parameters.
 - 2 load shape parameters
 - Optimized to match simulation force-displacement curves to tests results.

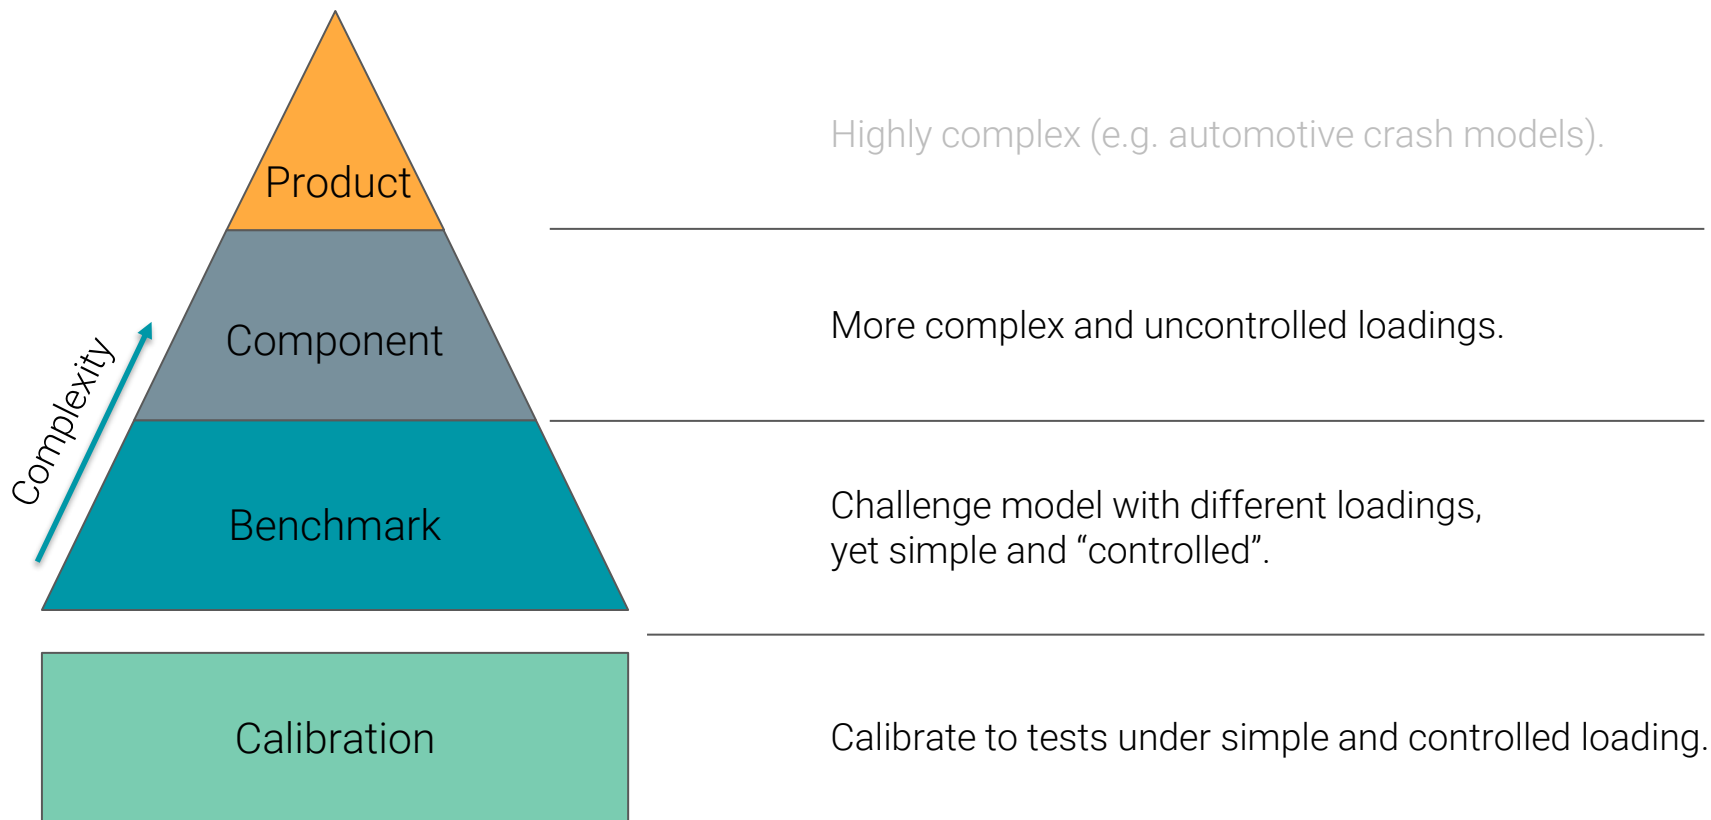

Limitations of macroscopic modelling of FDS

- Deformation and failure not always correctly predicted.
- Stress- and deformation fields are complex (rotation of screw, large plastic deformations and failure of plate material).
- Mimicking the global behaviour.
- Represented by mathematical constraints, the connection is not physically modelled.
- Geometric features (e.g. screw head and tail) not manifested in the model.

Calibration- and validation strategy

Connection and materials

Single-connector testing

Cross tests

Single-connector testing

Peel test

Single lap-joint test

Normal displacement

Tangential displacement

Simulations of single-connector tests

- 3 mm x 3 mm shell elements (ELFORM=16).
- Clamped parts modelled with *MAT_RIGID.
- Surface-to-surface contacts.
- Time scaling applied (explicit analysis).
- Material model:
 - Hershey-Hosford yield surface ($a=8$).
 - Voce isotropic hardening model.
- Connection modelled with *CONSTRAINED_SPR2.

Trick

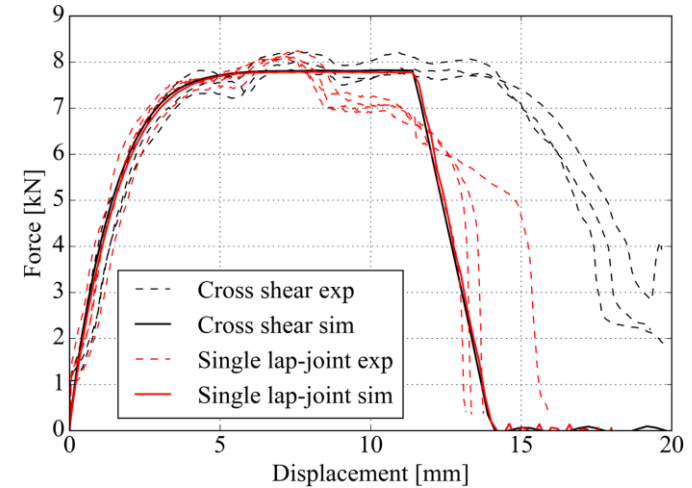

- Not correct deformation in peel test.
- A “head” of solid elements was modelled with `*MAT_ELASTIC` and `*CONTACT_TIED_NODES_TO_SURFACE`.

-> Better results.

Calibration of macroscopic FDS model

- Significantly different behaviour in cross shear and single lap-joint tests.
- Not captured by the connection model.
- Must make a choice.

Calibration of macroscopic FDS model

Cross

Single lap-joint

“Tail effect”

Peeling

Static component test and simulation

3 mm x 3 mm shell elements
(ELFORM=16).

Supports: *MAT_RIGID.

Impactor:
*RIGIDWALL_GEOMETRIC_FLAT_MOTION

Surface-to-surface contacts.

Time scaling applied.

FDS modelled with
*CONSTRAINED_SPR2 and "head".

Static component simulation

Effect of “head”

Local forces in connections

Tensile dominated

Remarks

- Proposed modeling strategy for FDS connections gives satisfactory results.
 - Limitation: component test give tensile dominated loads.
- Expensive and time consuming:
 - Macroscopic modelling of connections requires experimental tests for calibration and validation.
- Virtual testing:
 - Simulations on a smaller scale may be used to calibrate macroscopic models.

Virtual testing

Equivalent plastic strain

Dynamic component test and simulation

Similar simulation as the static case, but with

*`RIGIDWALL_PLANAR_MOVING_FORCES`

Dynamic component test and simulation

- Period with multiple impact hits longer in simulation, possibly due to lower initial stiffness.
- Similar behaviour after ~ 30 mm.
- Inertia forces in specimen did not alter the structural response.

Effect of...

Element size

Effect of ...

Friction coefficient between
specimen and supports

Friction coefficient between
component parts

Change of
deformation mode
